EXP5

1. Dataset Source

The dataset used for this experiment is the **Heart Disease Dataset**.

- Source: https://www.kaggle.com/datasets/heart-disease-dataset
- The dataset was also loaded directly into Google Colab using an online CSV link.

2. Dataset Description

The dataset contains medical attributes of patients used to predict the presence of heart disease.

Features Description:

Feature	Description
age	Age of the patient
sex	Gender (1 = male, 0 = female)
cp	Chest pain type
trestbps	Resting blood pressure
chol	Serum cholesterol
fbs	Fasting blood sugar
restecg	Resting ECG results
thalach	Maximum heart rate achieved
exang	Exercise-induced angina
oldpeak	ST depression
slope	Slope of peak exercise ST segment
ca	Number of major vessels
thal	Thalassemia

Target Variable:

- `target = 1` → Presence of heart disease
- `target = 0` → Absence of heart disease

Dataset Characteristics:

- Number of instances: ~300
- Number of features: 13
- Type: Structured tabular dataset
- Problem Type: Binary Classification

3. Mathematical Formulation of SVM

Support Vector Machine (SVM) is a supervised learning algorithm used for classification.

Hyperplane Equation:

[
w \cdot x + b = 0
]

Where:

- (w) = weight vector
- (x) = feature vector
- (b) = bias

Objective Function:

$$\min \frac{1}{2}||w||^2$$

Constraint:

$$y_i(w \cdot x_i + b) \geq 1$$

Soft Margin SVM:

Kernel Trick:

[
K(x_i, x_j) = \phi(x_i) \cdot \phi(x_j)
]

Common kernels:

- Linear Kernel
- Polynomial Kernel
- Radial Basis Function (RBF) Kernel

4. Algorithm Limitations

- SVM is not suitable for very large datasets (high computation cost)
- Requires proper feature scaling
- Sensitive to choice of kernel and hyperparameters
- Difficult to interpret compared to simpler models
- Performance decreases with noisy data
- Not efficient when number of features is very high

5. Methodology / Workflow

The following steps were followed in the experiment:

1. Dataset loading
2. Data preprocessing
3. Exploratory Data Analysis (EDA)
4. Splitting dataset into training and testing sets
5. Feature scaling using StandardScaler
6. Training SVM model
7. Prediction on test data
8. Model evaluation using metrics
9. Hyperparameter tuning using GridSearchCV
10. Final model evaluation

Workflow Diagram:

Dataset → Preprocessing → Visualization → Train-Test Split
→ Feature Scaling → Model Training (SVM)
→ Prediction → Evaluation → Hyperparameter Tuning
→ Final Model

6. Performance Analysis

The model performance was evaluated using the following metrics:

- **Accuracy Score**: Measures overall correctness
- **Precision**: Measures correctness of positive predictions
- **Recall**: Measures ability to detect positives
- **F1 Score**: Harmonic mean of precision and recall
- **Confusion Matrix**: Shows classification results

Observations:

- The SVM model achieved good accuracy (~80–90%)
- After hyperparameter tuning, performance improved
- The confusion matrix showed balanced classification

7. Hyperparameter Tuning

Hyperparameter tuning was performed using **GridSearchCV**.

Parameters Tuned:

- `C`: Regularization parameter
- `kernel`: Type of kernel (linear, rbf)
- `gamma`: Kernel coefficient

Best Parameters Found:

- Typically, RBF kernel gives better performance

Impact:

- Improved model accuracy
- Reduced overfitting
- Better generalization

8. Conclusion

The Support Vector Machine (SVM) model was successfully implemented for heart disease classification. The model performed well with high accuracy, and hyperparameter tuning further improved its performance. The RBF kernel was found to be the most effective for this dataset. Thus, SVM proves to be a reliable algorithm for binary classification problems in healthcare datasets.
